

MRI LUMBAR SPINE REPORT

Patient Name: Suresh Patil	Date: 2024-11-02
Age/Sex: 49 Years / Male	UHID: AD-H-23456
Ref Doctor: Dr. Venkat Rao	Accession No: 87654

Test Name: MRI Lumbar Spine (with contrast)**Clinical History:** Low back pain radiating to left leg for 3 weeks**Technique:** Multiplanar MRI of lumbar spine using T1, T2, STIR, and post-contrast sequences.**FINDINGS:**

The lumbar spine shows normal alignment. Vertebral body heights and signals are maintained. Intervertebral discs show varying degrees of signal loss.

At L4-L5 level, there is a posterolateral disc herniation measuring approximately 5mm, causing mild compression of the thecal sac and mild left neural foraminal narrowing.

At L5-S1 level, disc desiccation is noted without significant herniation.

Distal spinal cord appears normal in signal intensity and diameter.

No spinal canal stenosis or obvious facet arthropathy visualized.

Visualized paraspinal soft tissues are unremarkable.

IMPRESSION:

1. L4-L5 posterior left paracentral disc herniation causing mild thecal sac compression and mild left neural foraminal narrowing.
2. L5-S1 disc desiccation.
3. No cord compression or spinal canal stenosis.

Clinical correlation advised.
